

Overview.

The severity with the largest total of veteran compensation disability is the impaired severity. Total recipient compensation is explained across various statistical indicators, genders as well as correlation between total recipients and total population. The key findings, recommendations and a conclusion are broken-down in this summary.

Definitions.

Total Combined Rating - it measures the total impact of all service-connected conditions on a veteran's ability to function.

Total Combined Rating	Severity
0% -20%	Impaired
30% - 40%	Moderate
50% - 60%	Substantial
70% - 90%	Severe
100%	Total Disability

Mean - an average number.

Standard Deviation - it measures how spread out the data values are around the mean.

- High standard deviation - Spread out over a wider range indicating inconsistency.
- Low standard deviation - Close to the mean indicating consistency.

Key findings.

1. High Variability.

- Mean recipients by state: 1.00K
- Standard deviation: 1.46K

The standard deviation is larger than the mean, this suggests high variability across states. States like Vermont have 85 recipients, while states like California have 35,615 recipients. This distribution shows a disparity.

2. Gender Imbalance.

- Male: 91.19%
- Females: 8.81%.

Total recipients are 1.41 million, which is a substantial population for analysis.

However, given ratio of male vs female, it shows a strong gender imbalance. with compensation recipients being overwhelmingly male. This reflects military demographics.

3. Age Distribution.

Younger age groups (less than 35) appear smaller compared to middle-aged and older groups. The 55–64 range dominates the age analysis, suggesting compensation is most common among veterans in mid-to-late career or early retirement stages.

4. Severity of Impairment.

Recipients are spread across impaired, moderate, substantial, severe, and total disability categories. The South region and West region show higher totals in the impaired category.

5. Regional Patterns.

There is an uneven distribution of recipients across the Northeast, Midwest, South, and West. With states like California that are in the west consisting of the most recipients. Regions with higher total recipients in severe disability may need greater healthcare and support infrastructure.

Recommendations.

1. Healthcare support.

The West and South Region with higher totals in severe disability may need greater healthcare and support infrastructure. Age and severity patterns together can inform policy targeting (e.g., focusing resources on regions with older, severely impaired populations).

2. Gender.

To remedy the gender imbalance, the military could launch female related incentives in hopes that they volunteer more.

3. Lowering the Variability

In hopes to lower the Variability, the regions with fewer receipts should be educated on the benefits and incentives related to joining the military. The military could also invest in advertisements in the regions with fewer recipients.

Conclusion.

In conclusion, the USA military forces should focus on the regions, gender with the lower total receipts as well as health support in the regions with the highest severity numbers. Introducing various strategies to improve the ratio of female to male demographics will remedy the imbalance.
